A. Introduction

This report describes and illustrates the procedures for operating the Automatic Phase Picking System (APPS) for 5-day tapes. Since the early 1960's the USGS has deployed portable 3-component seismographs which originally recorded in analog format for 10.6 days on a 7200 ft. reel of tape. The first major use of these portable seismographs was at Parkfield, California after the 1966 earthquake. In 1970, the recording equipment was modified to operate at a tape speed of 5.3 days per reel. Originally data from these portable seismographs were retrieved by manually processing paper playbacks or by digitizing each event. In the last several years routine processing of data from the permanent network has become automated following the development of the Allen-Ellis Real Time Picker (RTP) microprocessor system (Allen, 1982). Development of the APPS in 1984 was an extension of this technology to the 5-day portable field seismographs consisting, essentially, of the addition of an RTP microprocessor system to the high-gain vertical component analog output of the 5-day tapes. The tapes are played out with a standard Bell and Howell playback unit at 20 times real-time. The phase records are collected on the UNIX 11/70 disk.

In the first use of the APPS, approximately 3600 aftershocks were picked from 114 reels of 5-day tapes recorded during the 1983 Coalinga, California aftershock sequence. The picks were later merged with those from the permanent CALNET stations and from other temporary networks. The resulting hypocenters and fault-plane solutions are reported in Eberhart-Phillips and Reasenberg (1985).

B. General Description of the System

The location of the components described below are shown in the diagram of the playback unit (Figure 1).

1. Hardware

Most of the APPS hardware is housed in the Bell and Howell Tape Drive Cabinet. Also included are the RTP boards, Time Code Translator (TCT), TCT amplifier, the WWVB and IRIG-C difference circuit, tape drive, and the necessary electronics for decoding and conditioning the WWVB and IRIG-C signals, as well as oscilloscopes for monitoring the seismic traces and time codes. A Televideo terminal allows communication with the UNIX PDP-11/70 and a switch box permits the computer to accept keyboard commands or RTP phase records.

2. Software

Four interactive UNIX processing programs allow the technician to edit, merge and sort the phase data produced by the APPS. Program 5DAYRTP reads the RTP output and adds the day, month, year and station name to the records. Program DRIFT calculates the time correction between WWVB and IRIG-C. Because the playback system reverses the sign on the time correction display unit, this program makes a sign correction in the phase file. Drift also deletes false phases (that is, phases with times before the start or after the end of the tape), and readings with times more than one day later than the previous

event. Program MRG5D combines and sorts the phase files into events creating one phase file for each day. Program MRGPL merges up to five HYP071 phase lists into a single phase list, creating one summary file and one phase file for each day.

3. Analog tapes, field notes and record keeping

The 5-day tapes are 1/2-inch, 8 channel, analog tapes. Each set of tapes that returns from the field is accompanied by a set of field notes containing pertinent information about station performance. Reading the field notes throughout the playback process is important because changes in station performance may occur in the field which effect processing. For example, gaps in the phase data are often the result of battery failure. Without field notes gaps in the data may be left unexplained. Setting up a note book to record drift readings, in-house and field equipment performance, is recommended. A three letter station abbreviation for each station sight must be established before the playback process begins. Drawing a record calendar of existing tapes provides a quick reference summary (see Figure 2). Labelling the tape box once a tape has been played back is also a useful part of the record keeping process.

C. Description of Components

1. The Scopes

There are three oscilloscopes located on top of the tape transport unit. The scope on the left displays the WWVB trace. The seismic signal is displayed on the center scope and the IRIG-C trace is displayed on the right scope.

2. The Tape Drive

The reels, rollers and tape heads make up the tape drive. The power panel to the right of the tape drive controls the tape drive unit. Below the tape drive is the Time Code Translator (TCT) which consists of two parts: the top section displays the corresponding Julian day, hour, minute and second tape time. The mode and filter settings are located in the lower section of the TCT below the digital display. The TCT error light is located on the bottom left corner of the seconds reading.

3. The Time Code Translator

A visual display of the time difference between IRIG-C and WWVB is necessary for time code corrections in the RTP phases. The time code correction or drift reading is located at the bottom of the main power panel. The correction must be read at least twice, once at the beginning and once at the end of each tape. Assuming a linear change in the time delay, program DRIFT calculates the time corrections for each phase read from the tape. The drift was assumed to be linear based on analysis of 114 tapes from 12 different stations. Errors based on an assumption of linear drift were smaller than the timing accuracy of the RTP (Figure 3).

4. The RTP

Within the tape drive unit is the RTP which times p-phases with respect to a translated IRIG-C time on the tape. The 5-day RTP samples 40 points per second tape-time (800 points per second real time) from one channel on the 5-day tape. This differs from the Calnet RTP which samples 200 points per second from 8 channels. Coda length is measured from the onset time to the time at which the amplitude falls and remains below 125 mv for 4 seconds. The first-motion polarities assigned by the RTP for 0-weight observations were judged to be accurate approximately 80% of the time, based on a comparison with 10 hand-picked events recorded in the Coalinga, California, 1983 aftershock sequence.

5. Card Chassis

FM Discriminators and Filters are located in the card racks in the bottom section of the cabinet below the TCT. There are three shelves of cards. The top shelf has 9 slots housing 5 cards. The WWVB and IRIG-C Discriminators are located in slots 1 and 2. Slot 3 houses the reference discriminator and slot 5 houses the reference conditioner and divider circuit. Slot 7 is the 5-day compensation/filter circuit and slot 9 is the WWVB vs IRIG-C phase compensation circuit. Slots 4, 6, and 8 are empty.

The middle shelf contains the four RTP cards. Card 1 is a single-board microprocessor. Card 2, (labeled A 13), supports the supervisor program and controls card 1. Card 3 is also a single-board microprocessor. Card 2 associates the signals it receives from card 1. Card 3 analyzes the results from card 4 (labeled 114).

The bottom shelf is the Tape Transport Electronics Tray. Slots 1 and 5 house the reproduce and direct reproduce cards respectively.

6. The Switch Box

Allows the computer to accept either keyboard commands or RTP phase output records. Card one of the RTP chassis, the Televideo and UNIX 11/70 are all connected to the switch box.

D. Controls and Correct Settings

1. The Scopes

Controls: The top left toggle switch labeled "vertical" on each scope allows the operator to check the zero line of the time code traces. When switched from REP (reproduce) to GRD (ground) the zero line appears.

Setting: The zero line must be centered to cross the middle of the time code so the tops of the IRIG and WWVB time code waveforms are above zero and the bottoms below zero. Adjustment of the zero line is done with the TCT amplifier. The zero line will be different for each tape but should not vary much within each tape. It is therefore necessary to check the zero line each time a tape is played.

2. The Tape Drive Unit

The Bell and Howell Tape drive is used in the normal fashion.

- 1) the ready light is ON when the tape is threaded tautly.
- 2) the phase lock selector set on TACH or TAPE
- 3) the record test selector set on NORM
- 4) the tape speed is 3 3/4 i.p.s.

3. Time Correction

The time code correction or drift reading is located at the bottom of the power panel. The time code translator error light must be off when taking a drift reading. If the error light is on, the drift reading is not fixed and will not be accurate. The time correction reading updates itself every 3 seconds.

4. Time Code Translator

If the playback unit remains assembled and operational, these settings will not need adjusting during the tape playing process. Fred Butler assembled the playback unit and maintains the equipment on a regular basis. Once the TCT has been set by Fred it should not need further adjusting.

5. The Switch Box

Controls: A toggle switch on the switch box allows information to be fed to the computer either directly from the RTP or interactively by the keyboard operator.

Setting: If the RTP is picking phases the switch box must be switched to PP. If the operator wants to communicate with the computer and the RTP is not picking phases the toggle switch should be set on T.

6. Booting the RTP

The RTP consists of four boards located in the middle card rack toward the bottom of the tape drive cabinet. The card in slot 2 (labeled A 13) has 2 toggle switches. The card in slot 4 (labeled 114) has 3 lights, a green and red light near the top and another red light at the bottom.

The picker is UP if the green light at the top of the 114 card is on and the red light at the bottom is flashing on and off. The RTP is DOWN when the green light is off and red light located directly below it stays on. To reset the RTP flip the top toggle switch on card A 13 up and down once.

If the picker goes down while processing a tape, a second phase file should be created by re-running program 5DAYRTP and later merging the two files together. If this occurs:

- 1) back up the tape to a point before the RTP failure
- 2) reboot the RTP
- 3) start program 5DAYRTP
- 4) start the tape, creating a new phase file
- 5) merge the phase files for the tape.

E. Running the Software Programs

See Figure 4 for software flowchart.

1. Running 5DAYRTP

Program 5DAYRTP reads the RTP output from the 5-day tape and adds the date and station names to the phases.

Example:

```
_?5dayrtp
  input your name
mari
  input station name - 3 letters
ESU
  input time of beginning of tape
month,day,hour,minute
88,11,01,13
  station = ESU
beginning  8 11    1 13
  Is this correct? (input Y or N)
y
Dear mari
System is now ready, to begin reading data directly from picker.
Switch to 'PP' when ready.
When tape is done, switch to 'T' and type in STOP
```

5DAYRTP will create a STA.phs phase file and a STA.out information file. (STA is the 3 letter station abbreviation).

2. Running DRIFT

DRIFT calculates the time correction between WWVB and IRIG-C.

Example:

```
_?drift
  input your name
mari
  input name of phase file
ESU0811.phs
  phase file = ESU0811.phs
  Is this correct? (input Y or N)
y
  input time of beginning drift reading
year,month,day,hour,minute
85,08,11,01,26
  input beginning drift, as read from playback display
0.05
  input time of ending drift reading
year,month,day,hour,minute
85,08,14,22,23
  input ending drift, as read from playback display
0.15
```

```
station = ESU
beginning 85 8 11    1 20  drift = 0.05
ending   85 8 14    22 23  drift = 0.15
```

Is this correct? (input Y or N)

```
Y
ESU0811.dph 7 8
***** ERROR IN INPUT ***** ESU XPD0 83 5 412 5 4.98
          0. -22
      skipping to next line
***** ERROR IN INPUT ***** ESU XPD0 83 5 412 721.61
          0. -13
      skipping to next line
***** ERROR IN INPUT ***** ESU XPD0 83 711 1 036.98
          0. -15
      skipping to next line
47 phases corrected for drift for station ESU
-?
```

(The ERROR IN INPUT message will appear if an event in the phase file occurred 2 days before the beginning tape time or 3 days after the end time).

a. Files created by DRIFT

DRIFT creates a STA.drf output log file and a STA.dph file of corrected phases with time corrections. Because the RTP lists all picks as 1983, the phases in the STA.dph file will need edited if the data is not from 1983.

3. Running MRG5D

MRG5D runs with a maximum of 12 STA.dph files. This program sorts the corrected phases into files that begin and end at midnight and combines events with less than 5 second time differences between consecutive P readings.

To Run MRG5D create a file containing the names of the STA.dph files to be merged. The command l *.dph > list.dph will work. Then to run mrg5d type:
MRG5D list.dph > MRG1.out

Example:

```
-?l *.dph > list.dph
?-cat list.dph
ELC0813.dph
EOM0814.dph
ESU0811.dph
ESU0814.dph
EYB0813.dph
list.dph
?-o list.dph
"list.dph" 6 lines, 69 characters
:sd
      5 EYB0813.dph
:wq
"list.dph" 5 lines, 60 characters
?-mrg5d list.dph > mrg1.out&
[1] 9776
-?
```

a. Files Created by MRG5D. The files created by MRG5D will be titled month and day followed by .phs1, .phs2 etc. (Example: 0811.phs1) A third run of MRG5D containing more phases for August 11 with create a 3rd .phs file (0811.phs3) The 0811.phs1, 0811.phs2, etc., files are hypo71 phase lists.

4. Running MRGPL. MRGPL merges up to five hypo71 phase lists or five 0811.phs1, 0811.phs2 etc. files together creating a single phase list and a summary list. For example: 0811.phs1 0811.phs2, 0811.phs3 would become one phase list called 0811.PL1. At this point other phase data maybe merged in with the 5-day phases.

To run MRGPL create a file containing the names of .phs files to be merged. The command 0814.phs* > list.pl will work. Then to run MRGPL type: mrgpl list.pl > pl.out

Example:

```
_?l 0814.phs* > list.pl
_?cat list.pl
0814.phs1
0814.phs2
0814.phs3
_?mrgpl list.pl > pl.out&
```

a. Files Created by MRGPL. The files created by MRGPL will be the month and day followed by .PL1 and .SL1. 0811.PL1 is a complete phase list for August 11th and 0811.SL1 is the summary file.

F. Operation Procedure

1. Before running a tape:

- 1) Establish three letter station abbreviations for each station sight.
- 2) Draw a calendar of existing tapes for a quick reference summary.
- 3) Label a binder and photocopy drift sheets to record necessary information.
- 4) Check the field notes for possible problems with the tapes or field equipment. Make sure the box label matches the information in the field notes and is copied correctly to the drift sheet.
- 5) Plan to label the tape boxes once the tape has been played.
- 6) Secure a jar of liquid freon and a supply of q-tips for cleaning the heads and rollers.

2. Running a tape:

- 1) Mount the data tape on the bottom reel with the tape label facing outward and fast reverse the tape to the top reel. REMEMBER, ALWAYS TAKE THE TAPES OFF THE HEADS WHEN USING FAST SPEEDS.
- 2) Clean the tape heads and rollers with liquid freon (NEVER USE RUBBING ALCOHOL).
- 3) Check the RTP lights. Does the system need booting up ?
- 4) Login UNIX, type '5dayrtp' and answer the prompts. (The 5dayrtp program will create a STA.phs file and a STA.out file, where STA is the 3 letter station abbreviation previously determined).
- 5) Thread the tape and push 'run fwd'.
- 6) Set switch box to pp.
- 7) Once the time signals are visable and the Time Code Translator has registered, and the TCT error light is off, record the drift reading and corresponding TCT reading on the drift sheet.
- 8) Check the time trace zero line by flipping the toggle switch on the scopes from REP to GRD. Remember that the tape plays at a speed up time of 20X real time so a 5-day tape that recorded in the field for 5 days should be finished in 6 hours.
- 9) Take a second drift reading and corresponding time from the end of the tape.
- 10) When the tape is finished put the switch box to 'T' and type 'stop'. Answer the prompts.
- 11) Rewind the tape.
- 12) Remove the tape, label the box and repeat the process. A tape can be mounted in the evening and left to run overnight. To do this repeat steps 1 thru 8. The next morning rewind the tape back far enough to record the end drift reading. Now repeat steps 9 thru 12.
